 - \cdot higher-twist effects in forward meson production ,
 - · anomalously large Single & Double Spin Asymetries,
 - \cdot factorisation breakdown in forward J/ψ production in pA

- Fixed-target experiments offer specific advantages that are still nowadays difficult to challenge by collider experiments
- They exhibit 4 decisive features,
 - accessing the high Feynman x_F domain ($x_F \equiv p_Z/p_{Z \max}$)
 - achieving high luminosities with dense targets,
 - varying the atomic mass of the target almost at will,
 - polarising the target.

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \text{ GeV}$

A .

∃ ▶ ∢

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

• In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

- In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger
- Benefit of the fixed target mode : boost: $\gamma_{CM}^{Lab} = \frac{\sqrt{s}}{2m_p} \simeq 60$

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

- In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger
- Benefit of the fixed target mode : boost: $\gamma_{CM}^{Lab} = \frac{\sqrt{s}}{2m_p} \simeq 60$
 - Consider a photon emitted at 90° w.r.t. the z-axis (beam) in the CM: $(p_{z,CM} = 0, E_{CM}^{\gamma} = p_T)$

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

- In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger
- Benefit of the fixed target mode : boost: $\gamma_{CM}^{Lab} = \frac{\sqrt{s}}{2m_p} \simeq 60$
 - Consider a photon emitted at 90° w.r.t. the z-axis (beam) in the CM:

•
$$\begin{pmatrix} E_{Lab} \\ \rho_{z,Lab} \end{pmatrix} = \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} \rho_T \\ 0 \end{pmatrix}$$
 $(p_{z,CM} = 0, E_{CM}' = \rho_T)$

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

- In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger
- Benefit of the fixed target mode : boost: $\gamma_{CM}^{Lab} = \frac{\sqrt{s}}{2m_p} \simeq 60$
 - Consider a photon emitted at 90° w.r.t. the z-axis (beam) in the CM:

•
$$\begin{pmatrix} E_{Lab} \\ p_{z,Lab} \end{pmatrix} = \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} p_T \\ 0 \end{pmatrix}$$
 $(p_{z,CM} = 0, E_{CM}^{T} = p_T)$

• $p_{z,Lab} \simeq 60 p_T$! [A 67 MeV γ from a π^0 at rest in the CM can easily be detected.]

Generalities

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

- In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger
- Benefit of the fixed target mode : boost: $\gamma_{CM}^{Lab} = \frac{\sqrt{s}}{2m_p} \simeq 60$
 - Consider a photon emitted at 90° w.r.t. the z-axis (beam) in the CM:
 - $\begin{pmatrix} E_{Lab} \\ p_{z,Lab} \end{pmatrix} = \begin{pmatrix} \gamma & \gamma \beta \\ \gamma \beta & \gamma \end{pmatrix} \begin{pmatrix} p_T \\ 0 \end{pmatrix}$ $(p_{z,CM} = 0, E_{CM}^{\gamma} = p_T)$
 - $p_{z,Lab} \simeq 60 p_T$! [A 67 MeV γ from a π^0 at rest in the CM can easily be detected.]
- Angle in the Lab. frame: $\tan \theta = \frac{p_T}{p_{z,Lab}} = \frac{1}{\gamma\beta} \Rightarrow \theta \simeq 1^\circ$.

[Rapidity shift: $\Delta y = tanh^{-1}\beta \simeq 4.8$]

Generalities

• pp or pA collisions with a 7 TeV p^+ on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$

- In a symmetric collider mode, $\sqrt{s} = 2E_{\rho}$, *i.e.* much larger
- Benefit of the fixed target mode : boost: $\gamma^{Lab}_{CM} = \frac{\sqrt{s}}{2m_{\rho}} \simeq 60$
 - Consider a photon emitted at 90° w.r.t. the z-axis (beam) in the CM:

•
$$\begin{pmatrix} E_{Lab} \\ p_{z,Lab} \end{pmatrix} = \begin{pmatrix} \gamma & \gamma \beta \\ \gamma \beta & \gamma \end{pmatrix} \begin{pmatrix} p_T \\ 0 \end{pmatrix}$$

 - $p_{z,Lab} \simeq 60 p_T$! [A 67 MeV γ from a π^0 at rest in the CM can easily be detected.]
- Angle in the Lab. frame: $\tan \theta = \frac{p_T}{p_{Z,Lab}} = \frac{1}{\gamma \beta} \Rightarrow \theta \simeq 1^\circ$.

[Rapidity shift: $\Delta y = tanh^{-1}\beta \simeq 4.8$]

• The entire forward CM hemisphere ($y_{CM} > 0$) within $0^{\circ} \le \theta_{Lab} \le 1^{\circ}$

 $[y_{CM}=0 \Rightarrow y_{Lab}\simeq 4.8]$

- Good thing: small forward detector \equiv large acceptance
- Bad thing: high multiplicity \Rightarrow absorber \Rightarrow physics limitation

- Let's adopt a novel strategy and look at larger angles
 - \cdot particles with sufficient p_T to be detected
 - \cdot heavy particles whose decay product have enough p_T to be detected

[not very heavy in fact: $J/\psi \rightarrow \mu\mu$ or $D \rightarrow K\pi$ are fine for current detectors]

A B b 4 B b

- Let's adopt a novel strategy and look at larger angles
 - \cdot particles with sufficient p_T to be detected
 - \cdot heavy particles whose decay product have enough p_T to be detected

[not very heavy in fact: $J/\psi
ightarrow \mu\mu$ or $D
ightarrow K\pi$ are fine for current detectors]

- Advantages:
 - · reduced multiplicities at large(r) angles
 - \cdot access to partons with momentum fraction $x \rightarrow 1$ in the target
 - · last, but not least, no geometrical constrain (e.g. beam pipe) at $\theta_{CM} \simeq 180^{\circ}$

Beam extraction

• Beam extraction @ LHC

... there are extremely promising possibilities to extract 7 TeV protons from the circulating beam by means of a bent crystal.

... The idea is to put a bent, single crystal of either Si or Ge (W would perform slightly better but needs substantial improvements in crystal quality) at a distance of $\simeq 7\sigma$ to the beam where it can intercept and deflect part of the beam halo by an angle similar to the one the foreseen dump kicking system will apply to the circulating beam.

... ions with the same momentum per charge as protons are deflected in a crystal with similar efficiencies

If the crystal is positioned at the kicking section, the whole dump system can be used for slow extraction of parts of the beam halo, the particles that are anyway lost subsequently at collimators.

★ The LHC beam may be extracted using "Strong crystalline field" without any decrease in performance of the LHC !

E. Uggerhøj, U.I Uggerhøj, NIM B 234 (2005) 31, Rev. Mod. Phys. 77 (2005) 1131

•

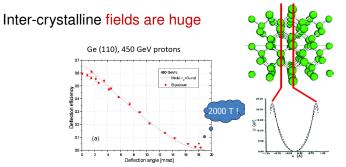

The channeling efficiency is high for a deflection of a few mrad
One can extract a significant part of the beam loss (10⁹p⁺s⁻¹)

J.P. Lansberg (IPNO, Paris-Sud U.)

pA studies with AFTER@LHC

May 10, 2013 33 / 29

- The channeling efficiency is high for a deflection of a few mrad
- One can extract a significant part of the beam loss $(10^9 p^+ s^{-1})$
- Simple and robust way to extract the most energetic beam ever:

pA studies with AFTER@LHC

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ s^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ s^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31
- Number of p^+ : 2808 bunches of $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ {
 m s}^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31
- Number of p^+ : 2808 bunches of $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ s^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31
- Number of p^+ : 2808 bunches of $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
 - the crystal sees $2808 \times 11000 \; s^{-1} \simeq 3.10^7 \; \text{bunches} \; s^{-1}$
 - one extracts $5.10^8/3.10^7 \simeq 15p^+$ from each bunch at each pass
 - Provided that the probability of interaction with the target is below 5%, no pile-up...

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ s^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31
- Number of p^+ : 2808 bunches of $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
 - the crystal sees $2808 \times 11000 \; s^{-1} \simeq 3.10^7 \; \text{bunches} \; s^{-1}$
 - one extracts $5.10^8/3.10^7 \simeq 15p^+$ from each bunch at each pass
 - Provided that the probability of interaction with the target is below 5%,
- Extraction over a 10h fill:
 - $5 \times 10^8 p^+ \times 3600 \text{ s } \text{h}^{-1} \times 10 \text{ h} = 1.8 \times 10^{13} p^+ \text{ fill}^{-1}$
 - This means $1.8 \times 10^{13}/3.2 \times 10^{14} \simeq 5.6\%$ of the p^+ in the beam

These protons are lost anyway !

no pile-up...

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ s^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31
- Number of p^+ : 2808 bunches of $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
 - the crystal sees $2808 \times 11000 \; s^{-1} \simeq 3.10^7 \; \text{bunches} \; s^{-1}$

W. J. Stirling

Department of Physics, University of Durham, Durham, England (Received 27 July 1987)

We perform a next-to-leading-order structure-function analysis of deep-inelastic μN and νN scattering data and find acceptable fits for a range of input gluon distributions. We show three equally acceptable sets of parton distributions which correspond to gluon distributions which are (1) "soft," (2)"-hard(") and (3) which behave as $\sigma(X) - 1/\sqrt{x}$ at small a. J/ϕ and promph hoton hadroproduction data are used to discriminate between the three sets. Set 1, with the "soft"-gluon ditribution, is favored. M, Z, and gir production data from the CERN collider are well described but do not distinguish between the sets of structure functions. The precision of the predictions for $\sigma \mu$ directly measured to DESY IERA.

LHB, a fixed target experiment at LHC to measure CP violation in B mesons

Flavio Costantini

University of Pisa and INFN, Italy

A fixed target experiment at LHC to measure CP violation in B mesons is presented. A description of the proposed apparatus is given together with its sensitivity on the CP violation asymmetry measurement for the two benchmark decay channels $B^0 \rightarrow J/\psi + K_s^0$, $B^0 \rightarrow \pi^+ \pi^-$. The possibility of obtaining an extracted LHC beam hinges on channeling in a bent silicon crystal. Recent results on beam extraction efficiencies measured at CERN SPS based on this technique are presented.

1. Introduction

•••

This paper presents a fixed target experiment to measure CP violation in the B system based on the possibility of extracting the 8 TeV LHC proton beam using a bent silicon crystal [4]. A 10% extraction efficiency of the LHC beam halo will give an extracted beam intensity of about 10⁸ protons/s allowing the production of as many as 10¹⁰ BB pairs per year, i.e. about two orders of magnitude more than what could be produced by an e⁺e⁻ asymmetric B factory with 10^{34} cm⁻³s⁻¹ luminosity [5].
