  - observation of surprising QCD phenomena
    - · breakdown of the Lam-Tung relation,
    - · colour transparency,
    - $\cdot$  higher-twist effects in forward meson production ,
    - · anomalously large Single & Double Spin Asymetries,
    - $\cdot$  factorisation breakdown in forward  $J/\psi$  production in pA
- Fixed-target experiments offer specific advantages that are still nowadays difficult to challenge by collider experiments
- They exhibit 4 decisive features,
  - accessing the high Feynman  $x_F$  domain ( $x_F \equiv p_Z/p_{Z \max}$ )
  - achieving high luminosities with dense targets,
  - varying the atomic mass of the target almost at will,
  - polarising the target.

### E866 at Fermilab with the Tevatron beam

– Precision  $\Upsilon$  studies in pp and pd collisions

E866 PRL 100 (2008) 062301

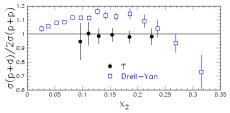

Precision: necessary to show a different behaviour from DY

## E866 at Fermilab with the Tevatron beam

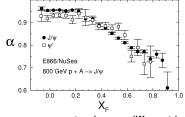

– Precision  $\Upsilon$  studies in pp and pd collisions

E866 PRL 100 (2008) 062301

Precision: necessary to show a different behaviour from DY

– Precision  $J/\psi$  and  $\psi(2S)$  studies in pA collisions  $_{ ext{E866 PRL 84}(2000) 3256}$ 

Precision: necessary to show a different behaviour of  $\psi(2S)$  vs.  $J/\psi$ 

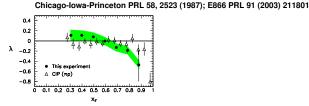

J.P. Lansberg (IPNO, Paris-Sud U.)

Using LHC Beams for Fixed Target Experiments

December 3, 2012 5 / 35

### E866 and before

- Precision  $J/\psi$  polarisation (in the CS frame) studies at large  $x_F$ 

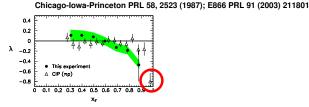

Precision and reach in  $x_F$ : necessary to show the change of pol. pattern

J.P. Lansberg (IPNO, Paris-Sud U.)

[Rapidity shift:  $\Delta y = tanh^{-1}\beta \simeq 4.8$ ]

• The entire forward CM hemisphere ( $y_{CM}>0)$  within  $0^\circ \leq \theta_{Lab} \leq 1^\circ$ 

 $[y_{CM}\,{=}\,0 \Rightarrow y_{Lab}\,{\simeq}\,4.8]$ 

- Good thing: small forward detector  $\equiv$  large acceptance
- Bad thing: high multiplicity  $\Rightarrow$  absorber  $\Rightarrow$  physics limitation

- $\sqrt{s}$  is large, let's adopt a different strategy and look at larger angles
  - $\cdot$  particles with sufficient  $p_T$  to be detected
  - $\cdot$  heavy particles whose decay product have enough  $p_T$  to be detected

[not very heavy in fact:  $J/\psi 
ightarrow \mu\mu$  or  $D
ightarrow K\pi$  are fine for current detectors]

- $\sqrt{s}$  is large, let's adopt a different strategy and look at larger angles
  - $\cdot$  particles with sufficient  $p_T$  to be detected
  - heavy particles whose decay product have enough  $p_T$  to be detected [not very heavy in fact:  $J/\psi \rightarrow \mu\mu$  or  $D \rightarrow K\pi$  are fine for current detectors]
- Advantages:
  - · reduced multiplicities at large(r) angles
  - $\cdot$  access to partons with momentum fraction  $x \rightarrow 1$  in the target
  - · last, but not least, no geometrical constrain (e.g. beam pipe) at  $\theta_{CM} \simeq 180^{\circ}$

Structure-function analysis and  $\psi$ , jet, W, and Z production: Determining the gluon distribution

> A. D. Martin Department of Physics, University of Durham, Durham, England

R. G. Roberts Rutherford Appleton Laboratory, Didcot, Oxon, England

W. J. Stirling

Department of Physics, University of Durham, Durham, England (Received 27 July 1987)

We perform a next-to-leading-order structure-function analysis of deep-inelastic  $\mu N$  and  $\nu N$ scattering data and find acceptable fits for a range of input gluon distributions. We show three equally acceptable sets of parton distributions which correspond to gluon distributions which are (1)  $\nu cohr, '12)$  hard(-m) and (3) which behaves as  $\sigma(X) - 1/\sqrt{x}$  at small x.  $J/\phi$  and promph hoton hadroproduction data are used to discriminate between the three sets. Set 1, with the "soft"-gluon distribution, is favored. W, Z, and gir production data from the CERN collider are well described but do not distinguish between the sets of structure functions. The precision of the predictions for  $\sigma u$ directly measured to Dilder are well described but do may a soft the collider measurements to yield information on the number of light neutrinos and the mass of the top quark. Finally we discuss how the gluon distribution at very small x may be directly measured at DESY HERA.

- In principle, one can get 300 times more  $J/\psi$  –not counting the likely wider *y* coverage– than at RHIC, allowing for
  - $\chi_c$  measurement in *pA* via  $J/\psi + \gamma$  (extending Hera-B studies)
  - Polarisation measurement as the centrality, y or  $P_T$
  - Ratio  $\psi'$  over direct  $J/\psi$  measurement in pA
  - not to mention ratio with open charm, Drell-Yan, etc ...

不得る 不良る 不良る

Observation of  $J/\psi$  sequential suppression seems to be hindered by

• the Cold Nuclear Matter effects: non trivial and

... not well understood

- the difficulty to observe directly the excited states which would melt before the ground states
  - $\chi_c$  never studied in AA collisions
  - ψ(2S) not yet studied in AA collisions at RHIC
- the possibilities for *cc* recombination
  - Open charm studies are difficult where recombination matters most

i.e. at low  $P_T$ 

• Only indirect indications –from the y and P<sub>T</sub> dependence of R<sub>AA</sub>–

that recombination may be at work

• CNM effects may show a non-trivial y and  $P_T$  dependence ...

### LHB, a fixed target experiment at LHC to measure CP violation in B mesons

Flavio Costantini

University of Pisa and INFN, Italy

A fixed target experiment at LHC to measure CP violation in B mesons is presented. A description of the proposed apparatus is given together with its sensitivity on the CP violation asymmetry measurement for the two benchmark decay channels  $B^0 \rightarrow J/\psi + K_s^0$ ,  $B^0 \rightarrow \pi^+ \pi^-$ . The possibility of obtaining an extracted LHC beam hinges on channeling in a bent silicon crystal. Recent results on beam extraction efficiencies measured at CERN SPS based on this technique are presented.

#### 1. Introduction

•••

This paper presents a fixed target experiment to measure CP violation in the B system based on the possibility of extracting the 8 TeV LHC proton beam using a bent silicon crystal [4]. A 10% extraction efficiency of the LHC beam halo will give an extracted beam intensity of about 10<sup>8</sup> protons/s allowing the production of as many as 10<sup>10</sup> BB pairs per year, i.e. about two orders of magnitude more than what could be produced by an e<sup>+</sup>e<sup>-</sup> asymmetric B factory with  $10^{34}$  cm<sup>-3</sup>s<sup>-1</sup> luminosity [5].

#### **Beam extraction**

#### • Beam extraction @ LHC

... there are extremely promising possibilities to extract 7 TeV protons from the circulating beam by means of a bent crystal.

... The idea is to put a bent, single crystal of either Si or Ge (W would perform slightly better but needs substantial improvements in crystal quality) at a distance of  $\simeq 7\sigma$  to the beam where it can intercept and deflect part of the beam halo by an angle similar to the one the foreseen dump kicking system will apply to the circulating beam.

... ions with the same momentum per charge as protons are deflected in a crystal with similar efficiencies

If the crystal is positioned at the kicking section, the whole dump system can be used for slow extraction of parts of the beam halo, the particles that are anyway lost subsequently at collimators.

#### Abstract

We outline the many physics opportunities offered by a multi-purpose fixed-target experiment using the proton and lead-ion beams of the LHC extracted by a bent crystal. In a proton run with the LHC 7-TeV beam, one can analyze pp, pd and pA collisions at center-of-mass energy  $\sqrt{s_{NN}} \simeq 115$  GeV and even higher using the Fermi-motion of the nucleons in a nuclear target. In a lead run with a 2.76 TeVper-nucleon beam,  $\sqrt{s_{NN}}$  is as high as 72 GeV. Bent crystals can be used to extract about  $5 \times 10^8$  protons/sec; the integrated luminosity over a year would reach 0.5 fb<sup>-1</sup> on a typical 1 cm-long target without nuclear species limitation. We emphasize that such an extraction mode does not alter the performance of the collider experiments at the LHC. By instrumenting the target-rapidity region, gluon and heavyquark distributions of the proton and the neutron can be accessed at large x and even at x larger than unity in the nuclear case. Single diffractive physics and, for the first time, the large negative- $x_F$  domain can be accessed. The nuclear target-species versatility provides a unique opportunity to study nuclear matter versus the features of the hot and dense matter formed in heavy-ion collisions, including the formation of the Quark-Gluon Plasma (QGP), which can be studied in PbA collisions over the full range of target rapidities with a large variety of nuclei. The polarization of hydrogen and nuclear targets allows an ambitious spin program, including measurements of the QCD lensing effects which underlie the Sivers single-spin asymmetry, the study of transversity distributions and possibly of polarized parton distributions. We also emphasize the potential offered by pA ultra-peripheral collisions where the nucleus target A is used as a coherent photon source, mimicking photoproduction processes in ep collisions. Finally, we note that W and Z bosons can be produced and detected in a fixed-target experiment and in their threshold domain for the first time, providing new ways to probe the partonic content of the proton and the nucleus

### Accessing the large x glue

PYTHIA simulation  $\sigma(y) / \sigma(y=0.4)$  statistics for one month 5% acceptance considered

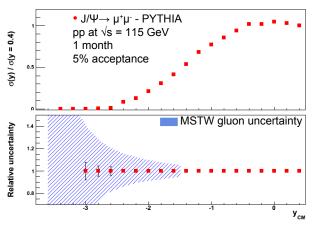

Statistical relative uncertainty Large statistics allow to access very backward region

Gluon uncertainty from MSTWPDF - only for the gluon content of the target - assuming

$$x_g = M_{J/\Psi}/\sqrt{s} e^{-yCM}$$

 $\begin{array}{l} J/\Psi \\ y_{\text{CM}} \sim \ 0 \ \rightarrow x_{\text{g}} = 0.03 \\ y_{\text{CM}} \sim -3.6 \ \rightarrow x_{\text{g}} = 1 \end{array}$ 

 $\begin{array}{l} \text{Y: larger } x_{g} \text{ for same } y_{\text{CM}} \\ y_{\text{CM}} \sim \ 0 \ \rightarrow x_{g} = 0.08 \\ y_{\text{CM}} \sim -2.4 \ \rightarrow x_{g} = 1 \end{array}$ 

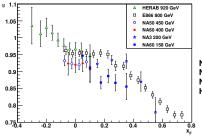

⇒ Backward measurements allow to access large x gluon pdf
